PROBLEM: ESTIMATE Y(t) FROM X(t) = x

• **Problem:** Given a vector observation X(t) = x, we would like to estimate y(t) via linear filter $\hat{y} = w^T x$ with minimized mean squared error (MSE).

• The objective (cost function) to be minimized is $MSE = \mathbb{E}\{[y(t) - w^T x]^2\}$. The filter design variables are w.

ESTIMATION

- What is Estimation?
 - In machine learning/signal processing/controls, often need to make predictions based on real world observations.
 - Process known as inference or estimation.

- What is LMMSE?
 - Estimates are given as linear combination of observations!

KEY IDEAS FOR RANDOM VECTORS

- Nx1 random vectors generalization of 2x1
- Complete statistical description vs Second moment description
 - Directional preference (KL expansion)
- Gaussian processes and linear processing
- Linearity of the expectation operator

$$\mathbb{E}\{L(\mathbf{x}(t))\} = L(\mathbb{E}\{\mathbf{x}(t)\})$$

expectation commutes with any linear operation

RANDOM VECTORS

random vector

$$\mathbf{X}(t) = \begin{bmatrix} X_1(t) \\ X_2(t) \\ \vdots \\ X_N(t) \end{bmatrix}$$
 $(N \times 1)$

Complete statistical description

$$p_{X(t)}(x) = p_{X_1(t), X_2(t), \dots, X_N(t)}(x_1(t), x_2(t), \dots, x_N(t))$$
(pdf or cdf or pmf)

$$m_X = \mathbb{E}\{X(t)\}$$

mean vector

$$\mathbf{R}_{\mathbf{X}} = \mathbb{E}\{\mathbf{X}(t)\mathbf{X}^{T}(t)\}$$

correlation matrix

Second Moment
Description

$$egin{aligned} [m{R}_{m{X}}]_{i,j} &= \mathbb{E}ig\{X_i(t)X_j(t)ig\} \ m{K}_{m{X}} &= \mathbb{E}ig\{(m{X}(t)-m{m}_{m{X}})(m{X}(t)-m{m}_{m{X}})^Tig\} & ext{covariance matrix} \ &= m{R}_{m{X}}-m{m}_{m{X}}m{m}_{m{X}}^T \end{aligned}$$

$$[K_X]_{i,j} = \text{Cov}[X_i(t), X_j(t)]$$

KARHUNEN-LOÈVE (KL) EXPANSION

Can always find orthonormal set of e-vectors of K

These are an alternate coordinate systems (rotations, reflections) in this eigen-coordinate system, the components are uncorrelated

"principal components"

The eigen-values are the variance (energy) in each principal directions

(reduce dimensions by "throwing out" low-energy components)

KL-EXPANSION

$$K_X e_k = \lambda_k e_k \ k = 1, 2, ..., N$$

Eigen equation

$$e_k^T e_l = \delta[k-l], \qquad \lambda_k \ge 0$$

$$\lambda_k \geq 0$$

orthonormal eigen vectors

$$X(t) = \sum_{k=1}^{N} X_k(t) \boldsymbol{e}_k$$

change of coordinates

$$X_k(t) = \boldsymbol{e}_k^T \boldsymbol{X}(t)$$

$$\mathbb{E}\{X_k(t)X_l(t)\} = \boldsymbol{e}_k^t \boldsymbol{K}_X \boldsymbol{e}_l = \lambda_k \delta[k-l]$$

uncorrelated components

$$K_X = \sum_{k=1}^N \lambda_k \boldsymbol{e}_k \boldsymbol{e}_k^t = \boldsymbol{E} \boldsymbol{\Lambda} \boldsymbol{E}^T$$

Mercer's Theorem

$$\mathbb{E}\{\|\boldsymbol{X}(t)\|^2\} = \operatorname{tr}(\boldsymbol{K}_{\boldsymbol{X}}) = \sum_{k=1}^{N} \lambda_k$$

Total Energy

Always exists because K_X is symmetric and positive semi- definite (PSD)

KL-EXPANSION EXAMPLE

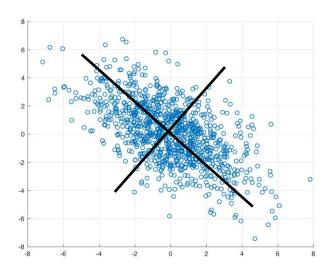

$$X(t) = H W(t)$$

$$\mathbf{H} = \begin{bmatrix} 1 & 2 \\ 1 & -2 \end{bmatrix}$$

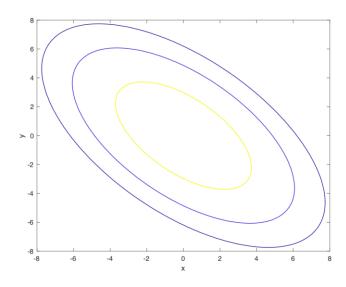

$$K = HK_WH^T = HH^T = \begin{bmatrix} 5 & -3 \\ -3 & 5 \end{bmatrix}$$

$$\boldsymbol{E} = \frac{1}{\sqrt{2}} \begin{bmatrix} +1 & +1 \\ +1 & -1 \end{bmatrix}$$

$$\mathbf{\Lambda} = \begin{bmatrix} 2 & 0 \\ 0 & 8 \end{bmatrix}$$

generated with W(t) Gaussian

Gaussian pdf contours

LINEAR/AFFINE MMSE (LMMSE AND AMMSE)

estimate Y(t) from X(t) = x

$$\min_{f(x)} E\left\{ \left\| y(t) - f(x(t)) \right\|^2 \right\}$$

with no constraint, this is the conditional expectation function

$$f_{\text{opt}}(x) = m_{y|X}(x)$$

$$= \mathbb{E}\{y(t)|X(t) = x(t)\}$$

$$= \int y \, p_{y|X}(y|x) dy$$

LMMSE ASSUMPTIONS

Assume that we know the second order statistics of the joint distribution $p_{X(t),Y(t)}(x,y)$

i.e.,
$$m_X$$
, m_Y , R_X , r_Y , r_{XY} .

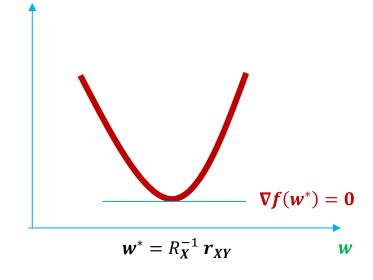

The objective is a quadratic function of w,

$$f(\mathbf{w}) = \mathbb{E}\{[Y(t) - \mathbf{w}^T \mathbf{x}]^2\}$$

= $r_Y - 2\mathbf{r}_{YX}^T \mathbf{w} + \mathbf{w}^T R_X \mathbf{w}$ $f(\mathbf{w})$

The global optimal occurs at w^* .

i.e.,
$$\nabla f(w)|_{w=w^*} = 0$$

MINIMUM MEAN-SQUARE ERROR ESTIMATION (MMSE)

Estimate y(u) from x(u) = x

cross covariance matrix

$$\mathbf{K}_{\mathbf{Y}\mathbf{X}} = \mathbb{E}\big\{(\mathbf{y}(\mathbf{t}) - \mathbf{m}_{\mathbf{Y}})(\mathbf{x}(\mathbf{t}) - \mathbf{m}_{\mathbf{X}})^{\mathrm{T}}\big\} = [\mathbf{K}_{\mathbf{Y}\mathbf{X}}]^{\mathrm{T}}$$

Affine MMSE

$$\min_{f(x)=Fx+b} \mathbb{E}\left\{ \left\| \mathbf{y}(t) - f(\mathbf{x}(t)) \right\|^2 \right\}$$

$$\mathbf{F}_{\mathsf{AMMSE}} = \mathbf{K}_{\mathbf{YX}} \mathbf{K}_{\mathbf{X}}^{-1}$$

$$\mathbf{b}_{\mathsf{AMMSE}} = \mathbf{m}_{\mathbf{y}} - \mathbf{F}_{\mathsf{AMMSE}} \mathbf{m}_{\mathbf{X}}$$

$$\min_{\mathbf{F}, \mathbf{b}} \mathbb{E}\{\|y(t) - [\mathbf{F}x(t) + \mathbf{b}]\|^2\}$$

$$\hat{\mathbf{y}} = \mathbf{K}_{\mathbf{Y}\mathbf{X}}\mathbf{K}_{\mathbf{X}}^{-1}(\mathbf{x} - \mathbf{m}_{\mathbf{X}}) + \mathbf{m}_{\mathbf{v}}$$

$$AMMS\varepsilon = Tr(\mathbf{K}_{\mathbf{Y}} - \mathbf{K}_{\mathbf{Y}\mathbf{X}}\mathbf{K}_{\mathbf{X}}^{-1}\mathbf{K}_{\mathbf{X}\mathbf{Y}})$$

Linear MMSE

$$\min_{\mathbf{f}(\mathbf{x})=\mathbf{F}\mathbf{x}} \mathbb{E}\left\{ \left\| \mathbf{y}(t) - \mathbf{f}(\mathbf{x}(t)) \right\|^2 \right\}$$

$$\mathbf{F}_{\mathsf{AMMSE}} = \mathbf{R}_{\mathbf{YX}} \mathbf{R}_{\mathbf{X}}^{-1}$$

$$\min_{\boldsymbol{F}} \mathbb{E}\{\|\boldsymbol{y}(t) - \boldsymbol{F}\boldsymbol{x}(t)\|^2\}$$

$$\hat{y} = R_{YX} R_X^{-1} x$$

$$LMMS\varepsilon = Tr(\mathbf{R}_{\mathbf{Y}} - \mathbf{R}_{\mathbf{YX}}\mathbf{R}_{\mathbf{X}}^{-1}\mathbf{R}_{\mathbf{XY}})$$

- affine often called linear... same when means are zero
- Conditional Expectation better than affine, affine better than Linear

PROOF FOR LMMSE

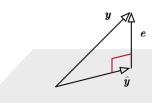

$$\min_F \mathbb{E}\{\|y(t) - FX(t)\|^2\}$$

Proof:

$$\begin{split} \text{MSE}(F) &= \mathbb{E}\{\|y(t) - FX(t)\|^2\} \\ &= \mathbb{E}\left\{\left\|\left(y(t) - F_{\text{opt}}x(t)\right) + \left(F_{\text{opt}} - F\right)x(t)\right\|^2\right\} \\ &= \mathbb{E}\left\{\left\|y(t) - F_{\text{opt}}x(t)\right\|^2\right\} + \text{Tr}\left(\left(F_{\text{opt}} - F\right)R_X(F_{\text{opt}} - F)^T\right) \\ &+ 2\,\text{Tr}\left(\left(R_{yx} - F_{\text{opt}}R_X\right)(F_{\text{opt}} - F)^T\right) \end{split}$$

if:
$$F_{opt}R_X = R_{XY}$$
 then: $MSE(F) = \mathbb{E}\left\{\left\|y(t) - F_{opt}X(t)\right\|^2\right\} + \underbrace{Tr\left(\left(F_{opt} - F\right)R_X\left(F_{opt} - F\right)^T\right)}_{\geq 0 \ \forall F, \ since \ R_X \ is \ psd}$

Wiener-Hopf equations, aka Orthogonality Principle

space of all estimates/approximations

because of orthogonality principle (error and signal uncorrelated)

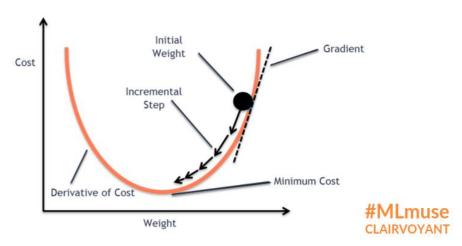

$$\mathbb{E}\{\|y(t) - \hat{y}(t)\|^2\} = \mathbb{E}\{\|y(t)\|^2\} + \mathbb{E}\{\|\hat{y}(t)\|^2\}$$
$$= \text{Tr}(R_v - R_{vx}R_x^{-1}R_{xv})$$

GRADIENT DESCENT

- Instead of obtaining optimal w^* directly, we can also find it iteratively via
 - 1. Initialize w_0

2.
$$\mathbf{w}_{n+1} = \mathbf{w}_n - \eta \ \nabla f(\mathbf{w}_n)$$

source: https://blog.clairvoyantsoft.com/

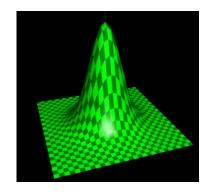

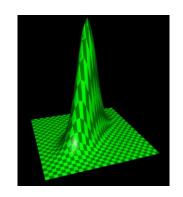

GAUSSIAN RANDOM VECTORS

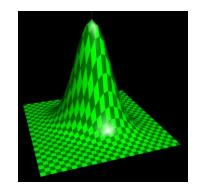

$$p_{x(t)}(x) = \mathcal{N}_N(x; m_x, K_X)$$

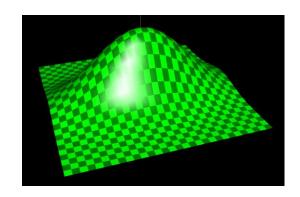

$$= \frac{1}{(2\pi)^{N/2} \sqrt{|K_x|}} \exp\left(-\frac{1}{2}(x - m_x)K_x^{-1}(x - m_x)\right)$$

$$\begin{aligned} p_{x(t)}(x) &= \mathcal{N}_{N}(x; 0, I) \\ &= \frac{1}{(2\pi)^{N/2}} \exp\left(-\frac{1}{2} \|x - m_{x}\|^{2}\right) \\ &= \prod_{k=1}^{N} \mathcal{N}_{1}(x_{k}; 0, 1) \end{aligned}$$

$$K = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$K = \begin{bmatrix} 1 & 0.7 \\ 0.7 & 1 \end{bmatrix}$$

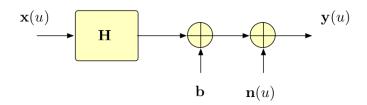

$$K = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \qquad K = \begin{bmatrix} 1 & 0.7 \\ 0.7 & 1 \end{bmatrix} \qquad K = \begin{bmatrix} 1 & -0.4 \\ -0.4 & 1 \end{bmatrix}$$

$$K = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}$$

$$K = \begin{bmatrix} \sigma_1^2 & \rho \sigma_1 \sigma_2 \\ \rho \sigma_1 \sigma_2 & \sigma_2^2 \end{bmatrix}$$

GAUSSIAN RANDOM VECTORS

any linear processing of Gaussians yields Gaussians

if
$$\begin{bmatrix} x(t) \\ n(t) \end{bmatrix}$$
 is Gaussian (i.e., $x(u)$ and $n(u)$ jointly-Gaussian), then:

y(t) is Gaussian

 $\begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$ is Gaussian

Jointly-Gaussian common in EE!

$$\begin{bmatrix} x(t) \\ n(t) \\ y(t) \end{bmatrix}$$
 is Gaussian

any subset of these random variables is also Gaussian

MMSE ESTIMATION: SPECIAL CASE JOINTLY-GAUSSIAN

Estimate y(u) from x(u) = x

Conditional Gaussian pdf:

$$p_{y(t)|x(t)}(y|x) = \frac{p_{X(t),Y(t)}(x,y)}{p_{X(t)}(x)}$$

$$= \frac{\mathcal{N}_{M+N}\left(\begin{bmatrix} x \\ y \end{bmatrix}; \begin{bmatrix} m_X \\ m_Y \end{bmatrix}, \begin{bmatrix} K_Y & K_{XY} \\ K_{YX} & K_Y \end{bmatrix}\right)}{\mathcal{N}_N(x; m_X, K_X)}$$

JG... no ML or deep learning needed!

$$= \mathcal{N}_{M}\left(y; \underbrace{m_{Y} + K_{YX}K_{X}^{-1}(x - m_{X})}_{\text{AMMSE estimator}}, \underbrace{K_{Y} - K_{YX}K_{X}^{-1}K_{XY}}_{\text{error covariance}}\right)$$

For JG observation and target: $\mathbb{E}[Y|x]$ is the Affine MMSE estimator

REMARKS

- 1. Closed-form global optimality can be derived if we have a convex and differentiable cost function.
- Gradient descent works in any differentiable cost function.
- 3. What if we don't have second order statistics but lots of samples?
 Use LMS!

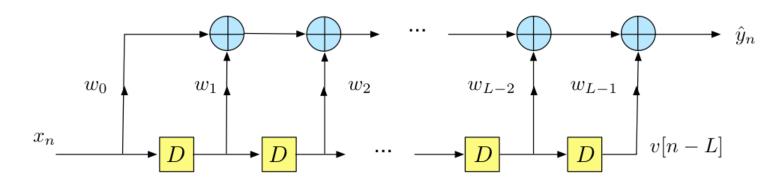

Single point gradient descent or small batch gradient descent!

 R_{x} computation not tractable for large number of samples

LMS ALGORITHM

- Suppose time index n and you have samples $\{(x_n, y_n)\}$ instead of the second order statistics then we use an online learning algorithm called least mean square **adaptive filtering**
 - Introduced by Widrow and Hopf (1959).

$$y_n = \sum_{l=1}^{N} w_l x_{n-l} = w^T v_n$$
 $w = \begin{bmatrix} w_1 \\ w_2 \\ \vdots \\ w_L \end{bmatrix}$ $v_n = x_{n-(L-1)} = \begin{bmatrix} x_n \\ x_{n-1} \\ \vdots \\ x_{n-L+1} \end{bmatrix}$

LMS ALGORITHM

- Assumptions:
 - Observe y(n) = s(n) + Noise and no access to the data signal s(n).
 - Have a reference noise signal x(n) with strong correlation to actual noise signal
- Why we need this?:
 - Slowly drifting interfering sinusoid so notch filter is insufficient
- Benefits:
 - Behaves as an adaptive notch filter
 - The notch can be very sharp, depending upon step size

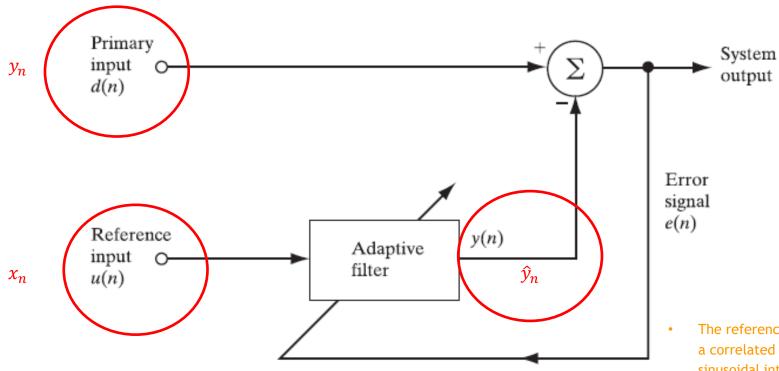

FIGURE 6.6 Block diagram of adaptive noise canceller.

- The reference input supplies a correlated version of the sinusoidal interference.
- For the adaptive filter, we may use an FIR filter whose tap weights are adapted by means of the LMS algorithm

Source: Simon Haykin, Adaptive Filter Theory (5th Edition), Pearson, Section 6.3, Application 4: Adaptive Noise Cancelling Applied to a Sinusoidal Interference

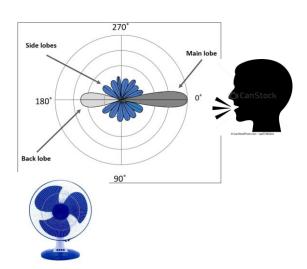

LMS HISTORY/EXAMPLE

Widrow and Hopf, Adaptive Linear Element (ADALINE) (developed LMS for adaptive antenna array processing)

point a beam at the desired speaker and *learn* to cancel noise energy in other directions using LMS

STEEPEST DESCENT AND LMS

Estimate y(u) from x(u) = x

$$E(w) = \mathbb{E}\{[y(t) - w^T x(t)]^2\}$$

$$\nabla_w E = 2\mathbb{E}\{wx(t)x^T(t) - y(t)x(t)\}$$
$$= 2(w^t R_x - r_{xy})$$

Steepest descent using (ensemble average) gradient:

$$\widehat{w}_{n+1} = \widehat{w}_n - \left(\frac{\eta}{2}\right) \nabla_w E$$
$$= \widehat{w}_n + \eta \left(r_{xy} - R_x \widehat{w}_n\right)$$

Single Point Stochastic Gradient Descent:

$$-\frac{1}{2}\nabla_{w}E = r_{xy} - R_{X}w$$

$$= \mathbb{E}\{y(t)X(t) - X(t)X^{T}(t)w\}$$

$$\approx y_{n}x_{n} - x_{n}x_{n}^{T}w$$

$$= (y_{n} - x_{n}^{T}\widehat{w}_{n})x_{n}$$

$$\widehat{w}_{n+1} = \widehat{w}_{n} + \eta(y_{n} - \widehat{w}_{n}^{T}x_{n})x_{n}$$

this is called "on-line learning"

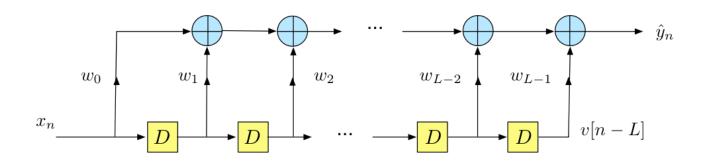

when $n \sim$ time, this is the **Adaptive** Least Mean Square (LMS) filter

when n does not represent time can average the gradient over more data points to improve approximation (batching)

USC Viterbi School of Engineering

LMS ALGORITHM IS ADAPTIVE FIR FILTER

$$y_n = \sum_{l=1}^{N} w_l x_{n-l}$$
$$= w^T v_n$$

$$w = \begin{bmatrix} w_1 \\ w_2 \\ \vdots \\ w_N \end{bmatrix}$$

$$v_n = x_{n-(L-1)} = \begin{bmatrix} x_n \\ x_{n-1} \\ \vdots \\ x_{n-L+1} \end{bmatrix}$$

Single Point Stochastic Gradient Descent:

$$-\frac{1}{2}\nabla_w E = r_{v_n y_n} - R_{v_n} w$$

$$= \mathbb{E}\{y(t)v_n(t) - v_n(t)v_n^T(t)w\}$$

$$\approx (y_n - w_n^T v_n)v_n$$

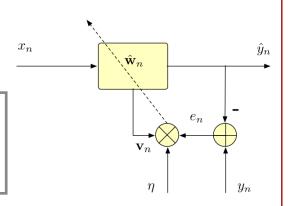

LMS Algorithm

$$\widehat{w}_{n+1} = \widehat{w}_n + \eta (y_n - w_n^T v_n) v_n$$

$$= \widehat{w}_n + \eta (y_n - \widehat{y}_n) v_n$$

$$= \widehat{w}_n + \eta e_n v_n$$

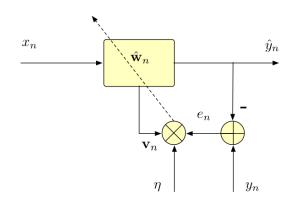

(an online linear regressor)

LMS ALGORITHM AS ADAPTIVE FIR FILTER

LMS algorithm: $\widehat{w}_{n+1} = \widehat{w}_n + \eta (y_n - w_n^T v_n) v_n$

If R_{v_n} and $r_{v_n y} = \mathbb{E}\{v_n(t)y(t)\}$ do not change with n,

$$\widehat{w}_n \rightarrow \approx w_{LMMSE} = R_v^{-1} r_{vy}$$

If these correlations vary with time, the LMS filter will adaptively track them

LMS ALGORITHM: FOR SINUSOIDAL NOISE CANCELLATION

Information bearing part

Sinusoidal noise

Primary input:

$$y(n) = s(n) + A_0 \cos(\omega_0 n + \phi_0)$$
 (1)

Reference input:

$$x(n) = A\cos(\omega_0 n + \phi)$$
 Same nature as Sinusoidal noise (2)

s(n) = information bearing signal / data signal.

LMS: get current estimate and error:

$$\hat{y}(n) = \sum_{i=0}^{L-1} \hat{w}_i(n) x(n-i)$$

$$= \hat{\mathbf{w}}_n^T \mathbf{v}_n$$
(3)

$$e(n) = y(n) - \hat{y}(n) = y(n) - \hat{\mathbf{w}}_n^T \mathbf{v}_n$$
(4)

Update filter tap weights:

$$\hat{\mathbf{w}}_{n+1} = \hat{\mathbf{w}}_n + \eta e(n) \mathbf{v}_n$$

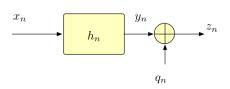

$$= \hat{\mathbf{w}}_n + \eta (y(n) - \hat{\mathbf{w}}_n^T \mathbf{v}_n) \mathbf{v}_n$$
(5)

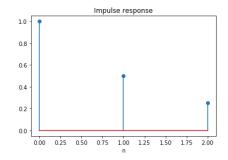

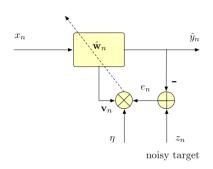

EXPERIMENT: LMS EXAMPLE

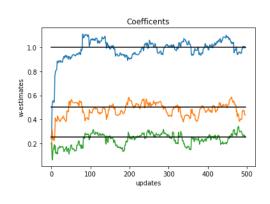

Generate data:

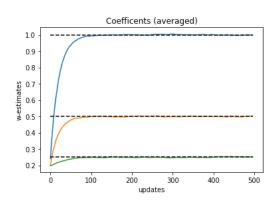

this is the ideal case where model and observed data are matched

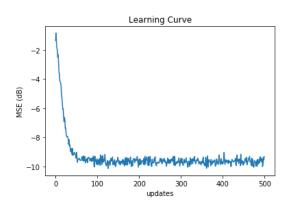

single run

 $\eta = 0.05$, SNR = 10 dB

averaged over 500 runs

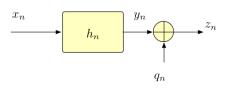

averaged over 500 runs

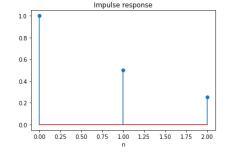

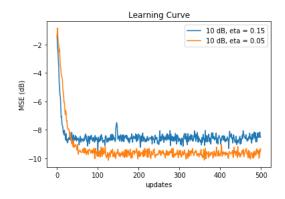

EXPERIMENT: LMS EXAMPLE

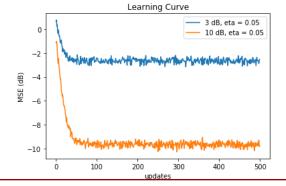

Generate data:

larger learning rate means faster convergence but more misalignment (gradient noise)

even the optimal Wiener (LMMSE) filter will have higher MMSE when the SNR is lower

EVOLUTION OF THE LMS ALGORITHM

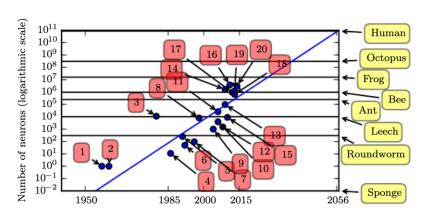

Figure 1.11: Increasing neural network size over time. Since the introduction of hidden units, artificial neural networks have doubled in size roughly every 2.4 years. Biological neural network sizes from Wikipedia (2015).

MMSE SUMMARY

- 1. Estimation using statistical models
- 2. Best MMSE estimator (unconstrained) is conditional expectation
 - Requires complete statistical description of observed and desired -i.e., p(y|x)
- 3. Linear/affine MMSE estimator have closed form equations
 - Require only the second moment description of observed and desired i.e.,
 means, correlations
- 4. For jointly Gaussian observed and desired 2 & 3 are the same!
- 5. The LMS algorithm is an algorithm that approximating the LMMSE cost function gradient with a single realization.
